1 Introduction

In this lab we used NASA's Hysplit to see how and which wind trajectories may be bring pollution to New Delhi. I chose the day - November 1st for my Analysis. Following are the results

2 Results

First we look at wind trajectories at 500 meters. November tends to be one of the most polluted months

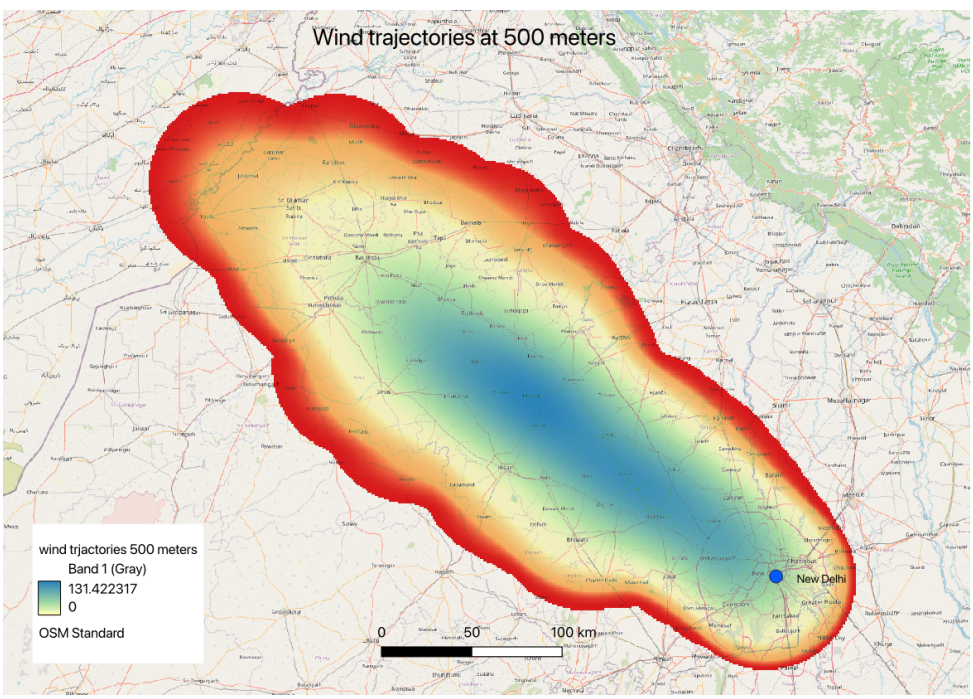

Figure 1: A larger concentration of the wind is from Punjab

We see that a large concentration of the wind comes from Punjab. Crop burning is prevalent during the month of November. Punjab also has a lot of Industries whose NOx and SOx could contribute to the pollution levels.

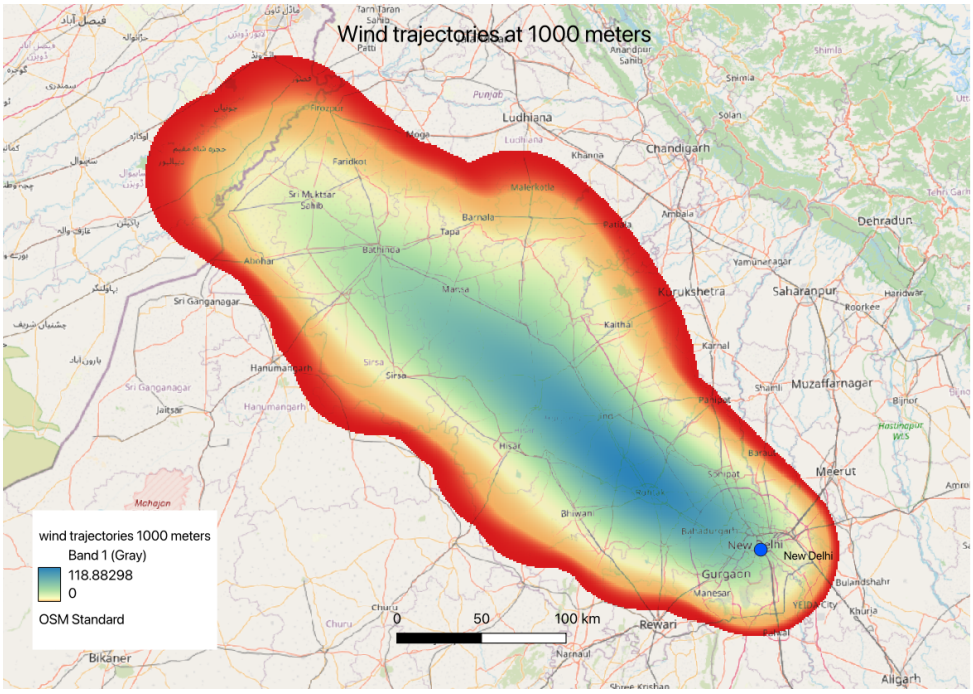

Figure 2: A large concentration of the windlfow appears to arise from the Bhatinda Area

The pollution again appears to aries from around Punjab. The Bhatinda area specifically. It has a large number of cement and chemical factories whose NOx, SOx and other pollutants have travelled towards New Delhi with the Wind
